(54) Abstract Title

Converting a standard logic execution unit to perform SIMD operations

(57) Microprocessor circuit 10 includes a standard execution unit which executes instruction 14 by performing a standard operation (e.g. an ALU operation or a Shift operation) on operands in registers 12. A correction circuit 20 modifies the results from the standard operation when instruction 14 is an SIMD (Single Input Multiple Data) instruction, and is bypassed for non-SIMD instructions. Arithmetic operations are corrected by operating on the results based on the significant bits and carry bits at the boundaries between the operand subsets (e.g. of Word or Double word size) on which the SIMD instruction operates (fig. 4). With Shift operations, a mask generator (76, fig. 5) is used in parallel with the Shifter (68, fig. 5) and modification of the standard shift results is performed by means of an address overlay mask. Use of the correction circuit 20 thus enables SIMD operations to be performed without the need for additional execution units.

This invention relates generally to data registers in microprocessor circuitry and more particularly to a Single Instruction Multiple Data (SIMD) correction circuit for modifying the results of an arithmetic/shift operation.

5 Heretofore, logic circuits have been proposed to improve performance of arithmetic/shift operations in data processing. With the increasing need for processing large amounts of data at ever increasing speed, improved efficiency of arithmetic/shift operations is very important. In particular, one of the difficulties of Multi-media, especially relating to graphics, is the large number of data that must be processed. An attribute of the Single Instruction Multiple Data (SIMD) is that each SIMD instruction can perform an operation
10 on each 8 bit, 16 bit, 32 bit, or 64 bit field of a 64 bit operand independently.

A SIMD ADD, for example, would perform an add on the first, second, third and fourth 16 bit section of the register operands as if the SIMD ADD were 4 independent 16 bit add instructions. A SIMD SHIFT, for example, would perform a shift on the first, second, third, and fourth 16 bit section of the register operands as if the SIMD SHIFT were 4
15 independent 16 bit SHIFT instructions. Also, the SHIFT operations include shift left, shift right logical, shift right arithmetic.

SIMD has gained recent popularity with the announcement of the Intel MMX Extension.

The MMX is a SIMD architecture. Implementing MMX extensions of the X86

architecture costs additional execution units dedicated to the MMX format. Converting a standard execution unit to perform both standard and SIMD operations introduces difficulties that have not heretofore been addressed. First, additional execution units adds delay to critical paths such as carry propagate paths since in SIMD the carry between SIMD sub-operands (16 bit or 32 bit sections) must be suppressed. Second, additional execution units requires additional silicon real estate (area). Third, additional execution units increases the development time and cost because the execution units are highly specialised circuits.

The present invention includes a correction circuit to convert a standard logic execution unit to perform both standard operations and SIMD operations. This invention has the advantages of alleviating the difficulty of delay to critical paths such as carry propagate paths; requiring less silicon space than if additional execution units were added; and does not require developing further highly specialised execution units. Execution units are highly specialised and thus to make a change to one is very labour intensive. This invention improves the performance of processing large amounts of data in applications such as Multi-media and signal processing.

This invention eliminates the critical paths, because logic is not added in the critical paths; saves time and silicon real estate because the same execution unit is being reused; and does not require the restructuring of a complex unit with added logic therein.

Another operation that requires processing large amounts of data which has application in both Multi-media and signal processing is matrix multiply. The present invention may be used on the standard logic of arithmetic/shift operations (e.g., ADD, SUBTRACT, DIVIDE, MULTIPLY, SHIFT) of Arithmetic Logic Units (ALUs) and Shift logic.

5 This invention includes a microprocessor circuit having an execution unit for execution of standard instructions in an arithmetic/shift operation and a correction circuit responsive to the execution unit for modifying the standard instructions provided by the execution unit to results required by a SIMD instruction being executed. This improves efficiency of the operations because the correction circuit modification may be performed in a
10 second cycle and the arithmetic/shift operation is free to execute a second instruction in the second cycle. The arithmetic/shift operation results from an instruction provided by either an Arithmetic Logic Unit (ALU) or by a shift function. The correction circuit passes data, unchanged for standard logical instructions but provides condition codes according to the SIMD instruction. The correction circuit corrects arithmetic operations
15 by operating on standard data based on significant bits and carry bits for sub-unit boundaries.

In the case of a Shift operation, this invention includes a Shifter performing standard operations on instructions in a first cycle of operation, a mask generating circuit in parallel with the Shifter circuit, and a correction circuit responsive to the Shifter and the
20 mask generating circuit for modifying the standard results provided by the Shifter to

results required by a SIMD Shift operation being executed. This modification may be performed by an address overlay mask in a second cycle operation and the Shifter is free to execute a second instruction in the second cycle.

5 How the invention may be carried out will now be described by way of example and with reference to the accompanying drawings in which like designations denote like elements, and:

FIG. 1 depicts a block diagram showing an execution unit for performing an arithmetic/shift operation and correction circuit of a first preferred embodiment in
10 accordance with the present invention.

FIG. 2 depicts a block diagram showing an execution unit for performing an arithmetic/shift operation unit and correction circuit of a second preferred embodiment in accordance with the present invention.

FIG. 3 depicts a high level view of a SIMD operation in accordance with a preferred
15 embodiment of the present invention.

FIG. 4 depicts a flow diagram disclosing a correction unit detail in accordance with a preferred embodiment of the present invention.

FIG. 5 depicts a flow diagram of a shift function in accordance with a preferred embodiment of the present invention.

20 FIG. 6 depicts mask generator detail in accordance with the present invention as depicted in Fig. 5.

FIG. 7 depicts AND/OR mask (AOM) detail in accordance with the present invention as depicted in Fig. 5.

FIG. 8 depicts a block diagram showing an execution unit/correction unit for a third preferred embodiment in accordance with the present invention.

5 Referring to Figure 1, a microprocessor circuit 10 of the present invention is shown with a correction circuit 20. The correction circuit 20 modifies the results of either standard operations of an ALU (Figure 4) or of standard operations of a Shifter (Figure 5-7) to results required by a SIMD instruction being executed. Standard execution unit 16 receives an instruction to be executed from a reservation station (s1) 15 which holds the
10 instruction 14 to be executed. The execution unit 16 provides access to registers 12 and performs either an ALU operation or a shifter operation. Finish stage (s2) 18 holds results to be written when the instruction 14 completes in the write-back stage.

A correction circuit 20 is shown including correction unit 22 and finish stage (s3) 24 for SIMD applications. In a first embodiment in Figure 1, the execution unit is depicted as a
15 two-stage pipeline. The first stage 17 to the pipeline enters the correction circuit 20 and the second stage 19 to the pipeline bypasses the correction circuit 20 to MUX 26 for non-SIMD operations. The results to registers 28 of the two pipelines 17, 19 are provided to the registers 12.

Figure 2 depicts a correction circuit 30 of a second embodiment of the present invention. This embodiment is similar to Figure 1 except that the MUX 26 is eliminated, permitting a SIMD or correction operation in the same cycle as a non-SIMD operation. A SIMD correction instruction is passed through flow line 29 and a non-SIMD instruction bypasses the correction unit 22 through flow line 31.

In yet another implementation Figure 8 shows a combined execution unit/correction unit 100. The correction stage could be performed by the ALU or shift operator of the execution unit/correction unit 100 by feeding the result 17. 101 of the first pass of the ALU or shift operator stage back to the ALU or shift operator with appropriate control hardware added. All of these implementations become obvious to one skilled in the art when taught the present invention and are therefore claimed by this disclosure.

SIMD Implementation Using Standard ALU

Figure 3 shows a high level view of a SIMD operation 40. An instruction 14 is depicted. A single SIMD instruction 44 performs operations simultaneously on subsets 7. 6. 5. 4. 3. 2. 1. 0 of the registers 12. As shown, Register operand (R2) 44 points to a 64 bit register 12. The operand instruction OP specifies the operation, for example, $R1 < -R1 + R2$ ADD instruction. The instruction 14 will perform independent adds on each subset 7 through 0.

Each subset 7 through 0 could be a single byte such that 8 independent adds are performed by the instruction using each of the 8 bytes in the 64 bit register operand. or the subset could be 16 or 32 bits.

Referring to Figure 4, the detail of the correction unit 20 of Figures 1 and 2 are depicted for use with a standard ALU. A 64 bit execution unit 16 has an eight byte result register 24. B7 is the high order byte, B(6),... with B(0) being the low order byte. Each of these bytes has three additional latches C(n), CI(n), and ZB(n). C(n) is the carry out of the high order bit of B(n) (the carry out of the byte), CI(n) is the carry into the high order bit of B(n), and ZB(n) indicates that all bits of B(n) are zero.

Each of these B(n) registers is connected to a box labeled F(n), the force box. F(n) has two input control lines plus the data from B(n). The input control lines are Force 8(n) and Force 0(n). Force 8(n) forces hex '80' on the output FB(n) of this box while Force 0(n) forces hex '00'. If both control lines are off then the input bus is passed to the output bus unmodified. The FB(n) byte output goes to a increment/decrement box ID(n). This box has two control inputs IB(n) and DB(n). IB(n) increments the input bus by one and DB(n) decrements the input bus by one. Both control lines being off passes the input bus to the output bus R(n) unmodified. ID(n) thus has a byte output bus and a output control line CB(n). This output is the CARRY/BORROW NOT line for the byte increment/decrement.

That is, it should be active when DB(n) is active AND FB(n)=X'00', OR when IB(n) is active FB(n)=X'FF'.

The following explains examples of the operations to be performed. While all combinations of these functions are not possible in the current SIMD definition the present invention contemplates all possibilities.

A number of instruction parameters are provided during the correction stage. First, Byte(B), Word (W), Double word(DW), and Quadword(QW) data size (where a word is 16 bits) is provided. Second, an ADD or SUBTRACT instruction is provided. Third, the instruction may be in signed or unsigned format. Signed numbers are standard two's complement format, while unsigned assumes only positive numbers. Fourth, these instructions are performed with either saturation or without. Without saturation means that results wrap if they exceed the specified size. With saturation means that if the results exceed the size then the largest or smallest number possible given the format is inserted. For example, in the case of an unsigned byte an overflow produces a result of 225 or hex 'FF' while an underflow (for subtract only) produces a result of 0 or hex '00'. For signed byte an overflow produces a result of 127 or X'7F' while an under flow (possible with add and subtract) produces a result of -128 or hex '80'.

The structure defined in Figures 1-4 allow for implementation of correction for all combinations of the above instruction parameter scenarios. Note that while the F-box produces the X'00' and X'80' directly the constants X'FF' and X'7F' are produced indirectly taking the X'00' and X'80' and decrementing by one.

5 In the simplest scenario ADD UNSIGNED BYTE (no saturation). The low order byte B(0) needs no correction. The next byte B(1) needs to be decremented by one if C(0)=1. Thus DB(1)=C(0). In general B(n) needs to be decremented by one if C(n-1)=1 or DB(n)=C(n-1).

10 For the ADD UNSIGNED WORD (no saturation) scenario, the result B(1)/B(0) needs no correction. The next word B(3)/B(2) needs to be decremented by one if C(1)=1. This means that DB(2)=C(1) and that DB(3)=CB(2). In general then DB(n)=C(n-1) and DB(n+1)=CB(n) where n=2, 4, 6.

15 ADD UNSIGNED DOUBLE WORD follows a similar pattern while ADD UNSIGNED QUADWORD needs no correction. It should also be obvious that the above pattern is identical for ADD SIGNED (no saturation).

In ADD UNSIGNED BYTE WITH SATURATION only overflow is possible, so only
 forcing X'FF' is required. The low order byte B(0) needs no decrementing but if C(0)=1
 then X'FF' should be forced. This is done by setting F0(0)=1 and DB(0)=1. Thus
 FO(0)=C(0) and DB(0)=C(0). The next byte B(1) needs to be decremented if C(0)=1 and
 5 needs to be forced to X'FF' if C(1)=1. Thus F0(1)=C(1) and DB(1)=C(0) OR C(1). Note
 that it is acceptable to force X'FF' in the case where C(1)=1 was caused by C(0)=1
 because the result ignoring C(0) must have been X'FF' anyway. So in general
 F0(n)=C(n) and DB(n)=C(n) OR C(n-1).

With regard to ADD UNSIGNED WORD WITH SATURATION, the low order word
 10 B(1)/B(0) does not need to be decremented but if C(1)=1 then both bytes need to be
 forced to X'FF'. Thus DB(1)=DB(0)=FO(0)=FO(1)=C(1). The next word B(3)/B(2)
 needs to be decremented if C(1)=1 and forced to X'FFFF' if C(3)=1. For B(2) then
 DB(2)=C(3) OR C(1) and FO(2)=C(3). For B(3) then FO(3)=C(3) and DB(3)=C(3) OR
 CB(2). In general FO(n+1)=FO(n)=C(n+1) and DB(n)=C(n+1) OR C(n-1) and
 15 DB(n+1)=C(n+1) OR CB(n) where n=2, 4, 6.

ADD UNSIGNED DW/QW WITH SATURATION follows a similar pattern.

In unsigned addition $C(n)$ represents overflow, while under flow could not happen. In signed addition underflow and overflow are possible so it is more complicated. Let $OV(n)=C(n)$ NOT AND $CI(n)$ represent overflow, while $UV(n)=C(n)$ AND NOT $CI(n)$ represent underflow and $V(n)=UV(n)$ OR $OV(n)$ represent some overflow/underflow condition.

ADD SIGNED BYTE WITH SATURATION requires forcing $X'7F'$ or $X'80'$. The low order byte $B(0)$ needs no decrementing but if $OV(0)=1$ then $B(0)$ needs to be forced to $X'7F'$ while if $UV(0)=1$ then $B(0)$ needs to be forced to $X'80'$. Thus and $X'7F'$ if $OV(1)=1$. Thus $F8(1)=V(1)$ AND $DB(1)=OV(1)$ OR $C(0)$. In general $F8(n)=V(n)$ and $DB(n)=OV(n)$)RC(n-1).

ADD SIGNED WORD WITH SATURATION adds complication. When detecting underflow or overflow the word must be forced to $X'8000'$ and $X'7FFF'$ respectively. Thus the low order byte must be forced to $X'00'$ and $X'FF'$ while the high order byte must be forced to $X'80'$ and $X'7F'$. The low order word $B(1)/B(0)$ does not need to be decremented but if $OV(1)=1$ then $B(1)/B(0)$ needs to be forced to $X'7FFF'$ and if $UV(1)=1$ then $B(1)/B(0)$ needs to be forced to $X'8000'$. Thus $F8(1)=F0(0)=V(1)$. $DB(0)=DB(1)=OV(1)$. The next word $B3/B2$ must be decremented if $C(1)=1$. forced to $X'7FFF'$ if $OV(3)=1$. and forced to $X'8000'$ if $UV(3)=1$. Thus $F(3)=F0(2)=V(3)$.

DB(2)=OV(3) OR C(1) and DB(3)=OV(3) OR DB(2). In general

$F8(n+1)=F0(n)=V(n+1)$, $DB(n)=V(n+1) \text{ OR } C(n)$, and $DB(n+1)=OV(n+1) \text{ OR } DB(n)$
for $n=2, 4, 6$.

5 ADD SIGNED DW/QW WITH SATURATION follows a similar pattern. The
SUBTRACT scenarios are the same as ADD except that instead of the correction
being decremented by one when carry in is one, it is incremented by one when carry in is
zero (borrow is one). Underflow and overflow are defined the same.

10 COMPARE FOR EQUAL and COMPARE FOR GREATER THAN take two operands
in the signed B, W, DW, or QW length add perform a compare. The result field is set to
all ones if true and all zeros if false. Given the ZB(n), C(n), and CI(n) signals it is trivial
to determine if the Byte, Word, Double word, or Quadword is EQUAL or GREATER
THAN. The structure defined already permits forcing all zeros and all ones.

Referring to Figure 4, the carry logic can be generated in many ways known in the art.

The figure implies a "ripple" arrangement but carry predict and carry look-ahead

15 techniques (for instance) may be used within the scope of the invention.

SIMD Shift Instruction With Standard Shifter

As shown in Figure 1 a reservation station (s1) 15 which holds the instruction to be executed. an execution unit 16 includes a SHIFTER (FIG.5), access to registers 12, and a finish stage (s2) 18 which holds results to be written when the instruction completes in the write-back stage. Figure 2 shows the present embodiment of the invention where the execution unit 16 is a two stage pipeline and SIMD correction is bypassed for non-SIMD instructions. This embodiment is more fully described above. The SIMD stage takes the result of the Shifter operation and corrects the sub-units to conform with the SIMD operation.

In another implementation of the invention the MUX 26 could be eliminated, permitting a SIMD instruction to complete in the same cycle as a single cycle instruction following it.

In yet another implementation of the present invention the correction stage 20 could be performed by the Shifter stage by feeding the result of the first pass of the Shifter stage back to the Shifter with the appropriate control hardware added. All of these implementations become obvious to one skilled in the art when we taught the present invention and are therefore encompassed by this disclosure.

Figure 3 shows the concept of the SIMD operation, a single SIMD instruction performs operations simultaneously on subsets of the register operands. Register (R2) 44 points to a 64 bit operand 12. The OP code specifies the operation (R1 < -R2 SHIFT instruction for instance). The SIMD instruction will perform independent SHIFTS on each subset. The subset could be a single byte such that 8 independent SHIFTS are performed by the instruction using each of the 8 bytes in the 64 bit register operand, or the subset could be 16 or 32 bits.

Figure 5 shows a high level view of a Shifter stage 60 of a preferred embodiment of the present invention. The shift Count (SCNT) 62, Operand 64 and Result regs 82 are part of the standard Shift Unit function for Non-SIMD instructions. A Mask Generator 76 uses the Operand 64 and Shift Count 62 to generate a Mask Reg (MR) 80 for the AND-OR Mask (AOM) 84 in parallel with the standard shift result. The Mask generator, MR, and AOM are the correction circuit as depicted in Figs. 1 and 2. The result of the AOM 84 is latched in the final result (second stage) register.

The details of the Mask Generator 76 are shown in Figure 6. The Left or Right shift indicator (L/R) 66 in conjunction with the Shift Count Register (SCNT) 62 creates a Shift Count Mask (SCNTM) 62. The Byte Shift Mask (BSM) 78 generates the shift mask for each byte of

Table 1. Byte Shift Mask (BSM) Function

SCNTM	BSM (7:0)
2 1 0	7 6 5 4 3 2 1 0
0 0 0	1 1 1 1 1 1 1 1
0 0 1	1 1 1 1 1 1 1 0
0 1 0	1 1 1 1 1 1 0 0
1 0 0	1 1 1 1 0 0 0 0
1 0 1	1 1 1 0 0 0 0 0
1 1 0	1 1 0 0 0 0 0 0
1 1 1	1 0 0 0 0 0 0 0

the 64 bit mask. This mask would be correct if it was a byte left shift with a count less than eight. ANDing the mask with the data produces the proper result for a shift left.

Table 2 describes the equations for deriving when the shift count is greater than or equal to a certain number. For example SCT8 is the equation for SCNT greater than or equal to 8. They are used in Table 3 to define the force X'00' (F0Sn) function for shift left and the force x'ff' (F1Sn) function for shift right.

Table 2. Shift Count Equations

SCT8	=S3+S4+S5+S6
SCT16	=S4+S5+S6
SCT24	=S5+S6+(S3 A S4)
SCT32	=S5+S6
SCT40	=S6-S5 A (S3 + S4)
SCT48	=S6- (S5 A S4)
SCT56	=S5 A S4 A S3
SCT64	=S6

Table 3. SHIFT LEFT AND SHIFT RIGHT

LEFT RIGHT	FOS7	FOS6	FOS5	FOS4	FOS3	FOS2	FOS1	FOS0
	FIS7	FIS5	FIS5	FIS4	FIS3	FIS2	FIS1	FIS1
5 BYTE LEFT	0	0	0	0	0	0	0	0
RIGHT	0	0	0	0	0	0	0	0
10 WORD LEFT	SCT16	SCT8	SCT16	SCT8	SCT16	SCT8	SCT16	SCT8
RIGHT	SCT 8	SCT16	SCT8	SCT16	SCT8	SCT16	SCT8	SCT16
DWORD LEFT	SCT32	SCT24	SCT16	SCT8	SCT32	SCT24	SCT16	SCT8
RIGHT	SCT8	SCT16	SCT24	SCT32	SCT8	SCT16	SCT24	SCT32
15 QWORD LEFT	SCT64	SCT56	SCT48	SCT40	SCT32	SCT24	SCT16	SCT8
RIGHT	SCT8	SCT16	SCT24	SCT32	SCT40	SCT48	SCT56	SCT64

At this point when the mask in the MR is AND/OR red with the 64 bit shifted data in the result register according to the function code defined in figure 7 the proper result is generated. The mask generated for shift left has ones where the data should be preserved and zeroes where it should be zeroed out. For shift right zeroes indicate the data should be preserved and ones indicate that zeroes or ones should be padded depending upon the kind of shift (arithmetic or logical) and the appropriate high order bit.

Table 4 shows the Generation of the function field which goes to the AOM. Referring to Figure 7, the AOM receives the MR and Result register for each byte and performs the function indicated in Table 5 based on the FN(X) field.

Table 4. FN(X) GENERATION¹

Operation:	FN7	FN6	FN5	FN4	FN3	FN2	FN1	FN0
SL (B,W,DW,QW)	01	01	01	01	01	01	01	01

CLAIMS

1. A microprocessor circuit comprising:

- a). arithmetic/shift function performing standard operations on instructions in a first cycle of operation; and
- b). a correction circuit responsive to said arithmetic/shift function for modifying the standard results provided by said arithmetic/shift function to results required by a Single Instruction Multiple Data (SIMD) instruction being executed.

2. The circuit of claim 1, wherein the correction circuit modification is performed in a second cycle.

3. The circuit of claim 2, wherein the arithmetic/shift function is free to execute a second instruction in the second cycle.

4. The circuit of claim 1, wherein the arithmetic/shift function and the correction circuit can each complete an instruction in the same cycle.

5. The circuit of claim 1, wherein the arithmetic/shift function is an instruction provided by an Arithmetic Logic Unit (ALU).

6. The circuit of claim 1, wherein the correction circuit passes data, unchanged for logical instructions but provides condition codes according to the SIMD instruction.

7. The circuit of claim 5, wherein the correction circuit corrects arithmetic operations by operating on standard data based on significant bits and carry bits for sub-unit boundaries.

5 8. The circuit of claim 5, wherein the standard ALU includes an ADD operation.

9. The circuit of claim 1, wherein the arithmetic/shift function is a SHIFT instruction.

10. A microprocessor circuit for executing Multi-Media instructions comprising:

a). an Arithmetic Logic Unit (ALU) performing standard operations on instructions in a first cycle of operation; and

10 b). a correction circuit responsive to the ALU for modifying the standard results provided by the ALU to results required by Single Instruction Multiple Data (SIMD).

11. The circuit of claim 1, wherein the correction circuit modification is performed in a second cycle.

12. The circuit of claim 2, wherein the ALU is free to execute a second instruction in the second cycle.

13. The circuit of claim 1, wherein the ALU and correction circuit can each complete an instruction in the same cycle.

14. A microprocessor circuit comprising:

- a). a Shifter performing standard operations on instructions in a first cycle of operation;
- b). a mask generating circuit in parallel with the Shifter circuit; and
- c). a correction circuit responsive to said Shifter and said mask generating circuit for modifying the standard results provided by said Shifter to results required by a SIMD SHIFT instruction being executed.

15. The circuit of claim 13, wherein the modification is performed in a second cycle.

16. The circuit of claim 14, wherein the modification is performed by an address overlay mask circuit.

17. The circuit of claim 14, wherein the Shifter is free to execute a second instruction in the second cycle.

18. The circuit of claim 13, wherein the Shifter and correction circuit can each complete an instruction in the same cycle.

5

19. The circuit of claim 13, wherein the Shifter performs a SHIFT operation.

20. A microprocessor circuit substantially as hereinbefore described with reference to and as shown in the accompanying drawings.
